Guideline for Caffeine Use in Preterm Infants

Main Author(s): Dr Katie Farmer, Dr Alison Pike, Dr Mel Guilder

Ratifying Committee: South West Neonatal Network Guideline Working Group

Date Ratified: 5th May 2016

Review Date: May 2019

Version: 01

KEYWORDS: Caffeine, Apnoea

The South West Neonatal Network comprises of NHS Trust Neonatal Units in the following locations: Southmead (Bristol), St Michael’s (Bristol), Yeovil, Gloucester, Bath, Barnstaple, Plymouth, Torbay, Truro, Exeter, Taunton, Swindon.

1. Scope of the Guideline
   The Guideline applies to all Units within the South West Neonatal Network and aims to standardise Caffeine use within the Network and provide auditable standards.

2. Definition of Terms

3. Overview – GUIDELINE FOR CAFFEINE USE IN PRETERM INFANTS

CAFFEINE FLOWCHART

Infant meets criteria for Caffeine:

↓

All infants:
- <30 weeks gestation or
- < 1500g birth weight
- Receiving CPAP from birth
- First 10 days preparing for extubation from ventilation

Consider for babies 30-34 weeks gestation if:
- Apnoea of prematurity
- Early extubation
- Weaning off IPPV
- Post-surgical procedures

↓

Loading and Maintenance dosage – refer to local Caffeine Citrate monograph
AND
Monitor oxygen saturations and heart rate

↓

STOP CAFFEINE:
- When infant has not required positive airway support or episodes of apnoea for at least 5 days
- At least 5 days prior to discharge

DISCONTINUE monitoring 48 hours after Caffeine stopped
4. Guideline for Caffeine Use in Preterm Infants

Introduction

- Apnoea of prematurity is defined as periods over 20 seconds of apnoea or less if associated with bradycardia and desaturation.
- Apnoea of prematurity is common but infants should be assessed to exclude other causes of apnoea such as sepsis, anaemia, NEC, encephalopathy, respiratory illness or apnoea secondary to medication.
- Methyl xanthines (Caffeine, aminophylline and theophylline) are used as respiratory stimulants to prevent apnoea and facilitate extubation. They stimulate the respiratory centre and increase the basal metabolic rate.
- Caffeine has a long half-life of around 100 hours, thus it can be safely given once daily and has less toxicity than the other methyl xanthines. It has a wider therapeutic to toxic ratio and has reliable enteral absorption.

Potential Benefits:

- Reduction in apnoea.
- Reduction in chronic lung disease.
- Improvement in extubation failure within 7 days.
- Prevention of postoperative apnoea.
- Diuretic effect.
- Reduction, although not statistically significant, in the incidence of severe retinopathy of prematurity.
- Improved rate of survival without neuro-developmental disability at 18-21 months corrected. This statistically significant improvement has not been shown to persist at 5 years, although there was a continuing reduction in severity of motor impairment.
- Improved white matter structure on MRI.

Potential Risks/Disadvantages:

- Tachycardia, agitation, tachypnoea, tremors, vomiting, jitteriness and seizures (symptoms of Caffeine toxicity).
- Potential to worsen gastro-oesophageal reflux.
- Transient decreased weight gain (first 3 weeks of life).
- No significant difference in death rate, severe hearing loss or necrotising enterocolitis but some studies have suggested a reduction in intestinal and cerebral blood flow.
- Possible association with nephrocalcinosis, particularly in conjunction with diuretic therapy.

Treatment Criteria:

Although there is no firm evidence it is suggested that Caffeine should be commenced in all infants.

- Less than 30 weeks gestation, or
- Birth weight less than 1500g.
This should be started immediately in babies receiving CPAP from birth and within the first 10 days during the process of preparing for extubation in ventilated babies.

Consider starting in 30-34 week gestation infants for:

- Apnoea of prematurity.
- Facilitating early extubation – aim to start 24hrs prior to planned extubation and within 6hrs of an unplanned extubation\(^1\).
- To wean off from positive pressure ventilation.
- Post-surgical procedures – as at increased risk of apnoeas\(^6\).

**Monitoring**

- Babies receiving Caffeine should have saturation and/or ECG monitoring.
- Monitoring can be discontinued 48 hours after Caffeine is stopped if clinically appropriate.

**Dosage and Regimen:**

Refer to local Caffeine citrate monograph (drugs folder/intranet).

- Loading dose: 20mg/kg intravenous (or oral if tolerating more than half fluid requirement as feed).
- Maintenance dose: 5-10mg/kg intravenously or oral, once daily, 24 hours after loading dose.

Routine levels are not required but consider checking if there is poor response to dosage increase or signs of possible toxicity\(^13\).

Review dose with weekly weight increase.

Stop Caffeine:

- The infant has tolerated at least 5 consecutive days without positive pressure support.
- The infant is free of apnoea for 5 days.
- At least 5 days prior to discharge.

5. **Monitoring Effectiveness**

**Audit Standards**

1. Prescribed dose of Caffeine citrate.
2. Gestation when Caffeine commenced..
3. Discontinuation of Caffeine when infant has not required positive airway pressure support or episodes of apnoea for at least 5 days.
4. Discontinuation of Caffeine at least 5 days prior to discharge.

APPENDIX 1: CAFFEINE CITRATE DRUG MONOGRAPH

CAFFEINE CITRATE
Intravenous/oral

PRESENTATION:
Caffeine citrate 10mg/ml, 1ml ampoule.
Caffeine citrate 10mg/ml, 5ml vial for oral use.
Peyona® (caffeine citrate) 20mg/ml, 1ml ampoule.

NB Caffeine citrate 2mg = caffeine base 1mg.
NB the products are not equivalent concentrations, check carefully.

USUAL DOSAGE:
Loading dose: 20mg/kg intravenously or orally if tolerating more than half fluid requirement as feed.

Maintenance dose: 5-10mg/kg intravenously or orally once daily, 24 hours after the loading dose.

RECONSTITUTION:
Already in solution.

ADMINISTRATION:
- Loading dose should be given over 30 minutes as an intravenous infusion or orally.
- Maintenance dose should be given over 10 minutes as an intravenous dose or orally.
- For infusion it may be diluted with sodium chloride 0.9% or glucose 5%.
- Flush line with 0.5ml of sodium chloride 0.9% between each drug.

pH: 2.5 (10mg/ml) when diluted with an equal quantity of sodium chloride 0.9%.
4.4 (20mg/ml) when diluted with an equal quantity of sodium chloride 0.9%.

ADDITIONAL INFORMATION:
- It is recommended that the solution, from the ampoules, is filtered prior to use. **Once solution drawn up from ampoules it must be transferred to an oral syringe if for oral dosage.**
- The solution is acidic and should not be given intramuscularly.
• In some cases maintenance doses of higher than 10mg/kg/day (expressed as caffeine citrate) may be required to achieve maximal efficacy.
• Intravenous administration should be by slow infusion rather than bolus injection to avoid sudden changes in blood pressure.
• Routine levels are not required but consider checking if there is poor response to dosage increase or signs of toxicity. Samples do not need to be collected at any set time.
